Introduction

This report contains the most current national estimates of teenage pregnancy, birth and abortion statistics available. It comprises tables containing annual national rates and numbers through 2008 and a discussion of the methodology and sources used to obtain the estimates.

Pregnancy rates include births, abortions and miscarriages; the pregnancy rate is not synonymous with the birthrate. Trends in rates of births, abortions and pregnancies can move in different directions and may be affected by different social and economic factors.

Previous versions of this report included data at both the national and state levels. In order to release information more quickly, we have included only national-level data in this report. A state-level report will follow when data are available.

Key findings

National levels and trends

- In 2008, nearly 750,000 women younger than 20 became pregnant: Some 733,000 pregnancies were among teenagers (women aged 15–19), and 13,500 were among those aged 14 and younger.
- The **pregnancy rate** among teenagers was 67.8 pregnancies per 1,000 women aged 15–19; this means that about 7% became pregnant.
- In 2008, the U.S. teenage pregnancy rate reached its lowest point in more than 30 years (67.8), down 42% from its peak in 1990 (116.9). Among women younger than 15, the pregnancy rate fell even more in that period (62%), from 17.5 to 6.6 per 1,000.
- The pregnancy rate among sexually experienced teenagers (those who had ever had intercourse) was 158.5 pregnancies per 1,000 women aged 15–19, reflecting the fact that the overall teenage pregnancy rate includes a substantial proportion of young people who have never had sex. The pregnancy rate among sexually experienced teenagers has fallen 29% since 1990, when it was 223.1.
- The teenage **birthrate** in 2008 was 40.2 births per 1,000 women. This was 35% lower than the peak rate of 61.8, reached in 1991.
- The 2008 teenage **abortion rate** was 17.8 abortions per 1,000 women. This figure is the lowest since abortion was legalized and 59% lower than its peak in 1988 (43.5).
- The long-term decline in teenage birth and abortion rates were interrupted by increases in 2006. By 2008, the declines had resumed.
- From 1986 to 2008, the proportion of teenage pregnancies ending in abortion (i.e., the abortion ratio) declined by one-third, from 46% to 31%.

National levels by race and ethnicity

- Among non-Hispanic white teenagers, the pregnancy rate has declined 50% since 1990 (from 86.6 per 1,000 to 43.3).
- The pregnancy rate among black women aged 15–19 fell 48% between 1990 and 2008 (from 223.8 per 1,000 to 117.0), but remains much higher than the non-Hispanic white rate.
- Among Hispanic teenagers (of any race), the pregnancy rate fell 37% from its highest level between 1992 and 2008 (from 169.7 per 1,000 to 106.6).
- Wide differences in birth and abortion rates also persist across racial and ethnic groups. The birthrate in 2008 for black and Hispanic teenagers was more than twice the rate for non-Hispanic white teenagers. The abortion rate among black teenagers was four times the rate for non-Hispanic whites, while the rate among Hispanic teenagers was twice the rate for non-Hispanic white teenagers.
- Following the 2010 national census, population counts for 2001–2009 were revised. Because pregnancy rates use these population counts in the denominator, the pregnancy rates for 2001–2006 in this report differ from those previously published. In particular, the revised population counts for Hispanic teens were higher than the intercensal estimates, resulting in new estimated pregnancy rates for Hispanic teens in 2001–2006 that are lower than previously published.

Discussion

The 1980s and early 1990s saw the highest pregnancy rates among teenagers in the United States. Birthrates also reached high points during this time. In contrast, abortion rates were relatively stable, after having increased during the 1970s. Thus, the increase in pregnancy rates from 1973, when abortion was legalized nationally, to 1980 was manifested mostly in a higher abortion rate, while the further increases in the pregnancy rate to its peak levels in the late 1980s and early 1990s resulted in increased birthrates. Since the mid-1990s, all three rates have steadily declined, while the birthrate has accounted for an increasing proportion of the total pregnancy rate.

Recent research concluded that almost all of the decline in the pregnancy rate between 1995 and 2002 among 18–19-year-olds was attributable to increased contraceptive use.¹ Among women aged 15–17, about one-quarter of the decline during the same period was attributable to reduced sexual activity and three-quarters to increased contraceptive use.¹

Overall rates of pregnancy and birth—and, to a lesser extent, rates of abortion—among teenagers and young women increased from 2005 to 2006, stayed relatively stable in 2007 and dropped slightly in 2008. Partial data suggest that the higher estimates in 2006 and 2007 were short-term fluctuations and that rates will resume a decreasing trend. The National Center for Health Statistics report of births for 2009 and 2010 show a further decrease in the birthrate among teenagers and those aged 20–24; births among teenagers aged 15–19 fell 15% from 2008 to 2010; and those among 20–24-year-olds fell by 12%. In both 2009 and 2010, the birth rates

among teenagers and young adult women were at historic lows.² Abortion data for 2009 and 2010 are not yet available; whether pregnancy rates experienced a similar decline can be determined once those data are obtained.

Other research has noted and seeks to provide additional explanations for the longer-term trends and changes, including shifts in the racial and ethnic composition of the population, increases in poverty, and changes in public perception and attitudes toward both teenage and unintended pregnancy.^{3–6}

Even with the recent reductions in teenage pregnancy, birth and abortion rates, the data presented here indicate that there are still large and long-standing disparities in rates by race and ethnicity. These disparities echo those seen among unintended pregnancy rates, which are several times higher among women of color than among white women.⁷

Trends in teenage pregnancy, birth and abortion will need to be closely monitored over the coming years to determine how the reproductive behaviors of young women in the United States may be changing. Further research will be needed to understand the factors that are affecting these trends.

Acknowledgments

This report was prepared by Kathryn Kost and Stanley Henshaw, with research assistance from Deva Cats-Baril, Carolyn Cox and Jesse Philbin. All are currently or formerly affiliated with the Guttmacher Institute. The report was made possible by a grant from The California Wellness Foundation (TCWF). The Guttmacher Institute also gratefully acknowledges the general support it receives from individuals and foundations, including major grants from The William and Flora Hewlett Foundation, The David and Lucile Packard Foundation and the Ford Foundation, which undergirds all of the Institute's work.

*All rates are the number of events per 1,000 women aged 15–19; pregnancy rate includes the estimated number of pregnancies ending in miscarriage or stillbirth. †The pregnancy rate among all 15–19-year-olds who have ever had sex. ‡The number of abortions per 100 pregnancies ending in abortion or live birth; denominator excludes miscarriages and stillbirths. §Pregnancy rates, birthrates and abortion ratios of non-Hispanic whites follow the NCHS methodology of including all white births of unknown Hispanic ethnicity with non-Hispanic births (<1% of all birth certificates).

Notes: In this and subsequent tables, data are tabulated according to the woman's age at the pregnancy outcome and, for births, according to the mother's race (not the child's). Numbers and rates may differ slightly from those published previously because we updated the population numbers from 2000 through 2008, using revised estimates of the intercensal populations based on the 2000 and 2010 censuses. We have also updated the proportion of all 15–19-year-olds who have ever had sex for 2003–2006 (see "National-level methods" in text), which affects the estimated pregnancy rates among sexually experienced teens for those years. u=unavailable.

Table 2.1 Among women aged 15–19, pregnancy, birth and abortion rates and numbers, and number of miscarriages, by year, 1972–2008

2008	6.6	2.8	2.9	13,520	5,764	6,010	1,750	2,046

*All rates are calculated as the number of events experienced by women aged 14 and younger divided by the female population aged 14. The denominator is limited to 14-year-olds because the majority of all pregnancies among women aged 14 and younger occur among those aged 14 (see methodology in text). The pregnancy rate includes the estimated number of pregnancies ending in miscarriage or stillbirth. †Includes stillbirths. ‡Denominator (population) is women aged 14. *Note:* u=unavailable.

*All rates are calculated as the number of events experienced by women younger than 20 (including those aged 14 and younger) divided by the female population aged 15–19. The denominator is limited to 15–19-year-olds because 97–98% of all pregnancies among women younger than 20 occurred among those aged 15–19. The pregnancy rate includes estimated number of pregnancies ending in miscarriage or stillbirth. †Includes stillbirths. ‡Denominator (population) is women aged 15–19. Note: u=unavailable.

Table 2.6 Among women aged 20–24, pregnancy, birth and abortion rates and numbers, and number of miscarriages, by year, 1972–2008

Year	Pregnancy rate*	Birthrate	Abortion rate	Total pregnancies	Births	Abortions	Estimated miscarriage†	Female population (in 1,000s)
1972	u	130.2	u	u	1,174,183	u	u	9,021

*All rates are the number of events per 1,000 women aged 20–24; pregnancy rate includes estimated number of pregnancies ending in miscarriage or stillbirth. †Includes stillbirths. *Note:* u=unavailable.

National-level methodology

The figures in these tables are based on data from the National Center for Health Statistics (NCHS) of the U.S. Department of Health and Human Services (number of births), the Guttmacher Institute (total number of abortions), the U.S. Centers for Disease Control and Prevention (distribution of women obtaining abortions by age, race and ethnicity), and the Population Estimates Program of the U.S. Bureau of the Census in collaboration with NCHS (population estimates). The exact sources are listed at the end of this section. We have adjusted the national age and race/ethnicity distributions of women obtaining abortions to ensure year-to-year comparability.

Pregnancies are the sum of births, abortions and miscarriages. Rates are calculated as the number of events per 1,000 women. Abortion ratios represent the number of abortions divided by the sum of abortions and births. Please note that in these tables, “age” refers to the woman’s age when the pregnancy ended. Consequently, the actual number of pregnancies that occurred among teenagers is higher than what is reported here because most of the women who conceived at age 19 had their births or abortions after they turned 20 and thus were not counted as teenagers. Likewise, please note that “year” refers to the calendar year in which the birth or abortion occurred, not when the conception occurred.

A small number of abortions performed between 1972 and 1975 were illegal. This report counts only legal abortions.

Some of the figures differ from those previously published by the Guttmacher Institute for two reasons. First, the estimates of the population counts for 2001–2006 have been revised using recently released updated counts of the population, which are based on the 2010 census (“intercensal estimates”). While most of the rates did not change dramatically, those for Hispanic teenagers did, with much lower rates for this group for 2001–2006, as compared with those based on the earlier population estimates projected by the Census Bureau. This was due to a larger number of Hispanic teenagers counted in the 2010 census than were projected from the 2000 census.

The second reason these estimates differ from those published previously is that we have revised our estimate of the proportion of women aged 15–19 who have ever had sex for 2003–2006. In our prior estimates, we used the estimate of this proportion from the 2002 National Survey of Family Growth (NSFG). For the current estimates, we obtained the proportion sexually experienced from the 2006–2010 NSFG and applied a proportion calculated by linear interpolation for each year from 2003 through 2005, using the proportions sexually experienced in 2002 and in 2006–2008. This difference affects only the rates among sexually experienced women.

The figures in this report may also differ from those found in other sources. First, as explained above, these data are not adjusted to reflect women’s age at conception or the year in which she conceived. Second, unlike some other reports, this one includes estimated numbers and rates of pregnancies ending in miscarriage. (Pregnancy rates excluding miscarriages can be calculated from the tables by summing the rates of birth and abortion.) The number of miscarriages was

estimated as 20% of births plus 10% of abortions; these proportions attempt to account for miscarriages that occurred after the pregnancy had lasted long enough to be noticed by the woman (i.e., 6–7 weeks after her last menstrual period).¹ Stillbirths are a very small proportion of all pregnancies; they are included in our estimates of miscarriages. In contrast to the 20%-10% approach we used, NCHS estimates miscarriages from survey respondents' reports of their pregnancies in the five years preceding the fielding of each round of the NSFG.² Third, the denominator we used in calculating rates among women younger than 15 is the female population aged 14, because most pregnancies occurring among these very young teenagers are among 14-year-olds (79% in 2008). The NCHS estimates use the number of women aged 10–14 for the denominator.³ Similarly, the denominator for rates among all women under age 20 is the female population aged 15–19 because from 1973–2008, 97–98% of all pregnancies to women younger than 20 were among those aged 15–19. Finally, denominators are based on population estimates that are produced by the Census Bureau in collaboration with NCHS for July 1 of each year and revised periodically; hence, our rates may differ slightly from those published elsewhere, depending on which year the population estimates were made (the “vintage”) or whether the rates have been updated using the intercensal population estimates available after each national census. For the years 1980, 1990 and 2000, NCHS uses the April 1 census counts and we use the July 1 estimates.

The percentage of 15–19-year-old women who were sexually experienced for the years 1982 and 1988 was obtained from Singh and Darroch.⁴ Linear interpolation was used to calculate the percentages for 1986 and 1987. For these two years only, “sexually experienced” was defined as having ever had sex after menarche. For the percentage of sexually experienced 15–19-year-olds from 1988 to 2002, we obtained the proportions of all 15–19-year-olds who had ever had sexual intercourse in 1988, 1995, 2002 and 2006–2008 from analyses of the NSFG. From 1988 on, “sexually experienced” is defined as having ever had sex, regardless of whether it occurred before or after menarche. Linear interpolation was used to calculate the percentages for the intervening years, 1989–1994, 1996–2001 and 2003–2005. These resulting percentages were applied to the population totals of 15–19-year-old women to calculate the number who were sexually experienced.
